

## National Exams December 2018

### 17-Ind-B1, Applied Probability & Statistics

3 hours duration

#### **NOTES:**

1. If doubt exists as to the interpretation of any question, the candidate is urged to submit with the answer paper, a clear statement of any assumptions made.
2. This is a closed book exam. Candidates are permitted to use one of the two permitted calculators (Sharp or Casio models).
3. Candidates are permitted to have an aid sheet consisting of one 8.5" x 11.0" sheet of paper. Writing is permitted on both sides of the paper.
4. This exam consists of three sections (A → C). Within each section, candidates will be given a choice of questions to answer. Please read the instructions for each section carefully. A breakdown of questions and marks is as follows:

Section A:            Do 2 of 4 Questions. Total marks: 20

Section B:            Do 2 of 3 Questions. Total marks: 40

Section C:            Do 1 of 2 Questions. Total marks: 20

Exam:                5 Questions.              Total marks: 100

4. The value of each question is listed in the exam. Remember to check the instructions for each section. DO NOT ATTEMPT TO DO ALL QUESTIONS.
5. Statistical tables are provided. If, for any reason, a value is missing, please note this and use an approximate value.

**Section A – Basic Concepts:** Complete two of the following **four** questions. This section is worth a total of 30 marks. Do not attempt all questions.

1. An Industrial Engineer analyzing a production process involving several assembly steps.
  - a. One particular assembly step involves attaching two steel plates with a screw. If the process step is assumed to be  $N(12, 3)$  seconds, what is the probability that an assembly requires more than 15 seconds to complete?
  - b. If a second step is added to the assembly process that is assumed to be  $N(10, 5)$  seconds, would it be considered unusual if the total time to complete the assembly took more than 28 seconds?
  - c. Is the normal distribution a reasonable assumption in this instance where we are looking at a task completion time? You may assume that the task will be repeated many times.

**10 Marks**

2. An industrial process is to undergo a design change. Prior to the design change, a sample of size 5 is taken, yielding an average of 10 with a standard deviation of 3. After the design change another sample of size 5 is taken, yielding an average of 4 with a standard deviation of 5. You may assume the process values are normally distributed.

- a. Test the following hypothesis using an  $\alpha$  of 0.05

$$\begin{array}{ll} H_0: & \bar{x}_1 = \bar{x}_2 \\ H_1: & \bar{x}_1 \neq \bar{x}_2 \end{array}$$

- b. Test the following hypothesis using an  $\alpha$  of 0.05

$$\begin{array}{ll} H_0: & \bar{x}_1 = \bar{x}_2 \\ H_1: & \bar{x}_1 > \bar{x}_2 \end{array}$$

- c. Reconcile your results from (a) and (b) and provide guidance if management wishes to determine if the process change has resulted in a process improvement of at least 1, where lower values are considered to be better.

**10 Marks**

3. A firm uses two shipping companies to transport its finished goods from Canada to Europe. A sample of 5 shipping completion times from each company appears below, with the shipping time in days.

A	B
35	38
30	26

33	37
27	32
32	32

- a. Analyze the samples using whatever method you feel is appropriate and determine if one shipping firm provides faster deliveries than the other.
- b. Discuss the issues around appropriate statistical tests for this instance. What statistical elements should management be aware of when conducting a comparison?
- c. Assume you have been tasked with completing the analysis of the two shipping companies. Briefly describe how you would complete the analysis. I am not looking for a rehash of the method from your answer to (a), but rather a *plan* for collecting and analyzing data that reflects the issues identified in (b).

**10 Marks**

- 4. Suppose a continuous random variable  $x$  has the probability density function  $f(x)$  given below:

$$f(x) = \begin{cases} 0 & \text{if } x \leq 0 \\ \frac{2x}{R^2} & \text{if } 0 < x < R \\ 0 & \text{otherwise} \end{cases}$$

- a. Prove that this function is a valid probability density function
- b. Find the mean of the function
- c. Find the variance of the function

**10 Marks**

**Section B – Intermediate Concepts:** Complete **two** of the following **three** questions.  
 This section is worth a total of 30 marks. Do not attempt all questions.

- As part of a recent study of patients undergoing a particular medical treatment, researchers recorded the demographics of patients in their study, specifically looking at the relationship between body mass index (BMI) and age. The data is below:

Patient	1	2	3	4	5	6	7	8	9
BMI	20	21	30	20	26	22	24	18	36
Age	45	34	40	32	28	30	52	33	47

- Fit a regression model for age (x) versus BMI (y) of the form  $y = ax + b$
- Test for the significance of the regression using  $\alpha = 0.05$ .
- Determine whether the coefficient for x is significant.
- Give the expected BMI for a 42 year-old individual and determine if we would consider a 42 year old with a BMI of 28 to be a statistical anomaly.

**20 Marks**

- Each year the Bluenose Marathon is run in Halifax, Nova Scotia in May. The route includes a loop on the Halifax peninsula and a loop across the harbour in Dartmouth, with runners crossing a bridge between the two loops. The organizers have traditionally alternated the loops: one year the Halifax loop is done first; the next year the Dartmouth loop is done first. The course is quite hilly, with particularly bad hills on the Dartmouth loop. The weather in May can be quite variable as well.

A random sample of actual data from 10 finishers from two years of the race is presented below:

Halifax 1st	Dartmouth 1st
203	207
209	222
225	229
239	240
255	247
260	247
261	250
262	252
263	260
279	265

- a. Determine, using  $\alpha = 0.01$  whether the variances from the two populations are the same. (You may assume that the populations are approximately normal distributed.)
- b. Using this information, develop a hypothesis test to test whether the difference in finishing time between the two routes is actually 0. Use  $\alpha = 0.1$
- c. State any assumptions that you have made in developing your hypothesis test.
- d. Find the approximate p-value for this test and provide interpretation about what the p-value means.
- e. Regardless of the statistical significance you found in (b), describe two or three potential sources of bias in the data sample and suggest a mechanism (or mechanisms) for resolving them.

**20 Marks**

- 3. Edison Motors is manufacturing a new line of electric scooters. They have three manufacturing facilities producing the same vehicles. Below is a sample of the number of labour hours required to complete a vehicle (in hours).

A	B	C
118	158	227
118	155	215
135	152	215
126	167	221
130	157	217

- a) Use Bartlett's test to test the hypothesis at the 0.05 level of significance that the population variances of the three growth records are equal.
- b) Assuming that labour hours is normally distributed, determine using ANOVA whether the plant significantly affects time to build. You may assume, for ease of calculations, that SST is 23047.6 and SSE is a number approximately equal to 460 (it is in fact not exactly 460 – please calculate SSE if possible. If you cannot find SSE, use the value 460).
- c) Using Tukey's test ( $\alpha = 0.05$ ) to determine which, if any, of the plants has a significantly different growth pattern than the other.

**20 Marks**

**Section C – Advanced Concepts:** Complete one of the following two questions. This section is worth a total of 20 marks. Do not attempt all questions.

- A variable ( $y$ ) was observed at different combinations of values of controlled variables  $x_1, x_2, x_3$ . The results are shown below.

$x_1$	$x_2$	$x_3$	$y$
85	12	7	2.15
66	18	10	1.09
74	17	8	1.26
80	15	6	1.57
85	16	7	1.92

The relation between  $y$  and  $(x_1, x_2)$  is assumed to be linear in the region of interest, find the least squares regression model for this data set. To aid you in your calculations assume the following:

$(X'X):$

5	390	78	38
390	30682	6026	2922
78	6026	1238	602
38	2922	*	**

- Determine the missing values for the  $(X'X)$  matrix.
- If  $(X'X)^{-1}$  is given below:

322.8483	-2.5213	-4.0284	-8.3081
-2.5213	0.0204	0.0273	0.0661
-4.0284	0.0273	0.1197	0.0047
-8.3081	0.0661	0.0047	0.4055

Find the least squares linear regression model for this data set.

- Complete the ANOVA table for this regression model and determine whether the linear model is a significant predictor of  $y$ . For ease of calculations, you may assume that  $SST = 0.7815$  and  $SSR = 0.7749$
- Determine if the  $x_2$  coefficient in your model is significant at the 95% level.
- Develop a 95% Confidence Interval and a 95% Prediction Interval for  $(x_1 = 80, x_2 = 15, x_3 = 5)$ . Explain the difference between the two (i.e. explain the difference between a CI and a PI).

**20 Marks**

2. You are an IE employed by the Northern Regional Health Authority (NRHA) to develop a simulation of the Albert Memorial Hospital in Bapaume, Nova Scotia. You are preparing to conduct a series of screening runs, using a design of experiments approach, to test patient flow policies via a simulation model. Your screening experiment includes two factors under management control: off-servicing and discharge planning. Off-servicing refers to the policy of allowing patients of one service (i.e. medicine) to be housed in a bed of another service (i.e. surgery). Discharge planning is a management policy which specifies that certain nursing staff members are assigned full time responsibility for planning a patient's discharge on admission (i.e. arranging home care, searching for space in nursing homes, etc.) Both controls are binary: they can be implemented or not. You may assume that implemented is the high setting and not implemented is the low setting.

The partial design matrix for this problem is listed below:

Run	Factors	
	A	B
1	-1	-1
2	1	-1
3	-1	1
4	1	1

- Complete the design matrix for this experiment and interpret the meaning of the settings (i.e. tell me what the signs mean in terms of the control factor settings, the main effects, and the interaction effects). You may assume that Factor A refers to the off-servicing policy, while Factor B refers to the discharge planning policy.
- Assume that you have completed five simulation replications of each run listed in the design matrix above. The following output gives the average number of beds occupied:

Run	Factors		Rep 1	Rep 2	Rep 3	Rep 4	Rep 5	Average
	A	B						
1	-1	-1	73.93	70.02	72.97	70.13	71.71	71.75
2	1	-1	69.53	68.80	71.40	71.52	71.53	70.56
3	-1	1	71.08	73.39	73.78	72.23	73.16	72.73
4	1	1	68.51	69.16	71.96	70.88	69.58	70.02

Complete an analysis of variance (ANOVA) on this output and determine which, if any, factors are significant. You may assume that SST = 53.17 and an alpha value of 0.05.

**20 Marks**
